

## A Mechanical Analog

### Sum of the Forces

$$\Sigma F = mg - bv = ma$$

### Solve for the acceleration

$$g - \frac{b}{m}v = a = \frac{dv}{dt}$$

### Separate Variables

$$\frac{dv}{g - \frac{b}{m}v} = dt$$

### Integrate

$$\int_0^v \frac{dv}{g - \frac{b}{m}v} = \int_0^t dt$$

$$-\frac{m}{b} \left[ \ln\left(g - \frac{b}{m}v\right) - \ln(g) \right] = t$$

take exponential of both sides

$$\left(g - \frac{b}{m}v\right) / g = e^{-bt/m}$$

$$v(t) = \frac{mg}{b} (1 - e^{-bt/m})$$

## Physics 196 Chapter 31 Problem 66

The **bar** of mass  $m$  is pulled horizontally across parallel rails by a massless string that passes over an ideal pulley and is attached to a suspended **mass M**. The uniform magnetic field has a magnitude  $B$ , and the distance between the rails is  $\ell$ . The rails are connected at one end by a load resistor  $R$ . Derive an expression that gives the horizontal speed of the bar as a function of time.

### Induced current and Magnetic Field

$$\text{Faraday's Law} \quad \mathcal{E} = -\frac{d\Phi_B}{dt}$$

### FreeBody Diagrams

$$F_B = BIL$$

The magnetic flux is changing through the area bounded by the bar and the rails. According to **Faraday's Law** a changing magnetic flux will induce an **emf** in the circuit which will then produce a **current** which will then produce an **induced magnetic field** that will **oppose** the changing magnetic flux.

Looking at the diagram, the direction of the induced current is counterclockwise. This will produce a **magnetic field** that will add to the external magnetic field through the circuit. Since the arrows are pointing in the same direction there is a **repulsion** between the **induced** and the **external** magnetic fields to the right.

Since the magnetic flux is decreasing through the circuit the induced magnetic field will produce a force on the bar that will **oppose** this change.

## Sum of the Forces

$$\Sigma F_y = F_T - F_g = -Ma_y$$

$$\Sigma F_x = F_B - F_T = -ma_x$$

Falling Mass

$$a_y = a_x$$

Sliding Bar

$$F_T = mg - Ma$$

$$F_T = F_B + ma$$

We need to find the **induced magnetic force**

Solve for the acceleration

$$\Phi_B = BA \cos \theta$$

$$I_{ind} = \frac{\mathcal{E}}{R} = \frac{d\Phi_B}{dt} \frac{1}{R} = \frac{d(BA)}{dt} \frac{1}{R} = \frac{d(Blw)}{dt} \frac{1}{R} = Bl \frac{dw}{dt} \frac{1}{R} = \frac{Blv}{R}$$

$$F_B = BI_{ind}L = B\left(\frac{Blv}{R}\right)l = \frac{B^2l^2v}{R}$$

$$mg - Ma = F_B + ma$$

$$mg - F_B = Ma + ma$$

$$\frac{mg - F_B}{M + m} = a$$

$$\frac{mg - F_B}{M + m} = \frac{dv}{dt}$$

Now, we are set to solve for the velocity of the bar with respect to time

Let's reduce our stress and set

$$\frac{mg}{M + m} + \frac{B^2l^2v}{R(M + m)} = \frac{dv}{dt}$$

$$\alpha = \frac{mg}{M + m}$$

$$\beta = \frac{B^2l^2}{R(M + m)}$$

Separate Variables

$$\frac{dv}{\frac{mg}{M + m} + \frac{B^2l^2v}{R(M + m)}} = dt$$

Integrate

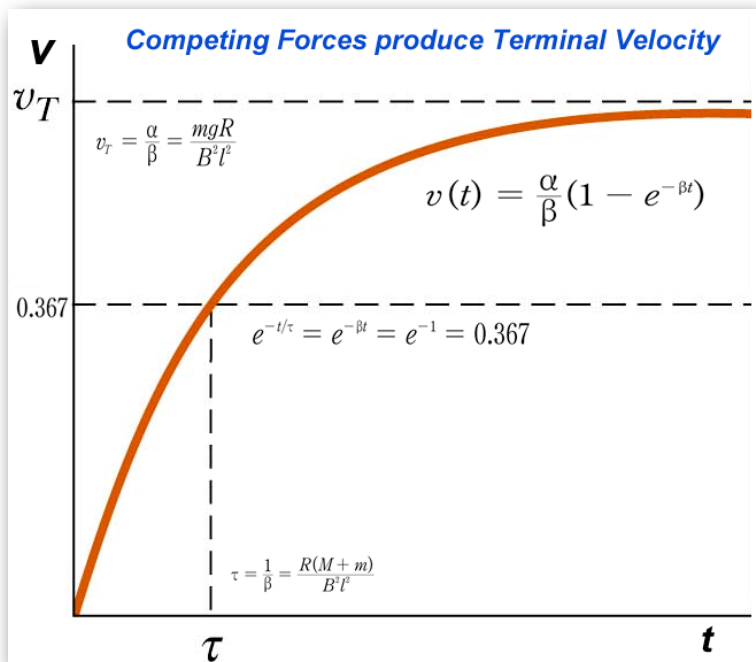

$$\int_0^v \frac{dv}{\alpha - \beta v} = \int_0^t dt$$

$$-\frac{1}{\beta} [\ln(\alpha - \beta v) - \ln \alpha] = t$$

$$\ln(\alpha - \beta v) - \ln \alpha = -\beta t$$

$$(\alpha - \beta v) / \alpha = e^{-\beta t}$$

$$v(t) = \frac{\alpha}{\beta} (1 - e^{-\beta t})$$

Over time, this **magnetic force** will balance with the **gravitational force** on the bar. This **magnetic force** is dependent upon the velocity of the bar. The bar will reach a terminal velocity once these two forces acting on the bar are equal.

## A Mechanical Analog

An object falling through a liquid reaches terminal velocity due to two competing forces.

$$\Sigma F = mg - bv = ma$$

Viscous Force  
Gravitational Force
